Abstract

This report presents a specification for the Portals 3.0 message passing interface. Portals 3.0 is intended to allow scalable, high-performance network communication between nodes of a parallel computing system. Specifically, it is designed to support a parallel computing platform composed of clusters of commodity workstations connected by a commodity system area network fabric. In addition, Portals 3.0 is well suited to massively parallel processing and embedded systems. Portals 3.0 represents an adaption of the data movement layer developed for massively parallel processing platforms, such as the 4500-node Intel TeraFLOPS machine.

[†]This work was supported by the United States Department of Energy under Contract DE-AC04-94AL85000.

Acknowledgment

Several people have contributed to the philosophy, design, and implementation of the Portals message passing architecture as it has evolved. We acknowledge the following people for their contributions: Al Audette, Lee Ann Fisk, David Greenberg, Gabi Istrail, Chu Jong, Mike Levenhagen, Jim Otto, Mark Sears, Lance Shuler, Mack Stallcup, Jeff VanDyke, Dave van Dresser, Lee Ward, and Stephen Wheat.

Glossary

API	Application Programming Interface. A definition of the functions and semantics provided by library of functions.
Group	The collection of <i>processes</i> loaded as a parallel job.
Initiator	A <i>process</i> that initiates a message operation.
Message	An application-defined unit of data that is exchanged between <i>processes</i> .
Message Operation	Either a put operation, which writes data, or a get operation, which reads data.
Network	A network provides point-to-point communication between <i>nodes</i> . Internally, a network may provide multiple routes between endpoints (to improve fault tolerance or to improve performance characteristics); however, multiple paths will not be exposed outside of the network.
Node	A node is an endpoint in a <i>network</i> . Nodes provide processing capabilities and memory. A node may provide multiple processors (an SMP node) or it may act as a <i>gateway</i> between networks.
Process	The instantiation of an executing program on a node.
Rank	Each <i>process</i> in a <i>group</i> is assigned a unique integer in the range 0 to n , where n is the number of <i>processes</i> in the <i>group</i> .
Target	A <i>process</i> that is acted upon by a message operation.

The Portals 3.0 Message Passing System

Revision 1.0

1 Introduction

1.1 Overview

This document describes an application programming interface for message passing between nodes in a system area network. The goal of this interface is to improve the scalability and performance of network communication by defining the functions and semantics of message passing required for scaling a parallel computing system to ten thousand nodes. This goal is achieved by providing an interface that will allow a quality implementation to take advantage of the inherently scalable design of Portals.

This document is divided into several sections:

Section 1—Introduction

This section describes the purpose and scope of the Portals API.

Section 2—An Overview of the Portals 3.0 API

This section gives a brief overview of the Portals API. The goal is to introduce the key concepts and terminology used in the description of the API.

Section 3—The Portals 3.0 API

This section describes the functions and semantics of the Portals application programming interface.

Section 4—The Semantics of Message Transmission

This section describes the semantics of message transmission. In particular, the information transmitted in each type of message and the processing of incoming messages.

Section 5—Examples

This section presents several examples intended to illustrate the use of the Portals API.

1.2 Purpose

Existing message passing technologies available for commodity cluster networking hardware do not meet the scalability goals required by the Cplant [1] project at Sandia National Laboratories. The goal of the Cplant project is to construct a commodity cluster that can scale to the order of ten thousand nodes. This number greatly exceeds the capacity for which existing message passing technologies have been designed and implemented.

In addition to the scalability requirements of the network, these technologies must also be able to support a scalable implementation of the Message Passing Interface (MPI) [7] standard, which has become the *de facto* standard for parallel scientific computing. While MPI does not impose any scalability limitations, existing message passing technologies do not provide the functionality needed to allow implementations of MPI to meet the scalability requirements of Cplant.

The following are properties of a network architecture that do not impose any inherent scalability limitations:

- Connectionless - Many connection-oriented architectures, such as VIA [3] and TCP/IP sockets, have limitations on the number of peer connections that can be established.
- Network independence - Many communication systems depend on the host processor to perform operations in order for messages in the network to be consumed. Message consumption from the network should not be dependent on host processor activity, such as the operating system scheduler or user-level thread scheduler.
- User-level flow control - Many communication systems manage flow control internally to avoid depleting resources, which can significantly impact performance as the number of communicating processes increases.
- OS Bypass - High performance network communication should not involve memory copies into or out of a kernel-managed protocol stack.

The following are properties of a network architecture that do not impose scalability limitations for an implementation of MPI:

- Receiver-managed - Sender-managed message passing implementations require a persistent block of memory to be available for every process, requiring memory resources to increase with job size and requiring user-level flow control mechanisms to manage these resources.
- User-level Bypass - While OS Bypass is necessary for high-performance, it alone is not sufficient to support the Progress Rule of MPI asynchronous operations.
- Unexpected messages - Few communication systems have support for receiving messages for which there is no prior notification. Support for these types of messages is necessary to avoid flow control and protocol overhead.

1.3 Background

Portals were originally designed for and implemented on the nCube machine as part of the SUNMOS (Sandia/UNM OS) [6] and Puma [11] lightweight kernel development projects. Portals went through two design phases, the latter of which is used on the 4500-node Intel TeraFLOPS machine [10]. Portals have been very successful in meeting the needs of such a large machine, not only as a layer for a high-performance MPI implementation [2], but also for implementing the scalable run-time environment and parallel I/O capabilities of the machine.

The second generation Portals implementation was designed to take full advantage of the hardware architecture of large MPP machines. However, efforts to implement this same design on commodity cluster technology identified several limitations, due to the differences in network hardware as well as to shortcomings in the design of Portals.

1.4 Scalability

The primary goal in the design of Portals is scalability. Portals are designed specifically for an implementation capable of supporting a parallel job running on ten thousand nodes. Performance is critical only in terms of scalability. That is, the level of message passing performance is characterized by how far it allows an application to scale and not by how it performs in a two-node ping-pong benchmark.

Portals are designed to allow for scalability, not to guarantee it. Portals cannot overcome the shortcomings of a poorly designed application program. Applications that have inherent scalability limitations, either through design or implementation, will not be transformed by Portals into scalable applications. Scalability must be addressed at all levels. Portals do not inhibit scalability, but do not guarantee it either.

To support scalability, the Portals interface maintains a minimal amount of state. Portals provide reliable, ordered delivery of messages between pairs of processes. They are connectionless: a process is not required to explicitly establish a point-to-point connection with another process in order to communicate. Moreover, all buffers used in the transmission of messages are maintained in user space. The target process determines how to respond to incoming messages, and messages for which there are no buffers are discarded.

1.5 Communication Model

Portals combine the characteristics of both one-side and two-sided communication. They define a “matching put” operation and a “matching get” operation. The destination of a put (or send) is not an explicit address; instead, each message contains a set of match bits that allow the receiver to determine where incoming messages should be placed. This flexibility allows Portals to support both traditional one-sided operations and two-sided send/receive operations.

Portals allows the target to determine whether incoming messages are acceptable. A target process can choose to accept message operations from any specific process or can choose to ignore message operations from any specific process.

1.6 Zero Copy, OS Bypass and Application Bypass

In traditional system architectures, network packets arrive at the network interface card (NIC), are passed through one or more protocol layers in the operating system, and eventually copied into the address space of the application. As network bandwidth began to approach memory copy rates, reduction of memory copies became a critical concern.

This concern lead to the development of zero-copy message passing protocols in which message copies are eliminated or pipelined to avoid the loss of bandwidth.

A typical zero-copy protocol has the NIC generate an interrupt for the CPU when a message arrives from the network. The interrupt handler then controls the transfer of the incoming message into the address space of the appropriate application. The interrupt latency, the time from the initiation of an interrupt until the interrupt handler is running, is fairly significant. To avoid this cost, some modern NICs have processors that can be programmed to implement part of a message passing protocol. Given a properly designed protocol, it is possible to program the NIC to control the transfer of incoming messages, without needing to interrupt the CPU. Because this strategy does not need to involve the OS on every message transfer, it is frequently called “OS Bypass.” ST [12], VIA [3], FM [5], GM [9], and Portals are examples of OS Bypass protocols.

Many protocols that support OS Bypass still require that the application actively participate in the protocol to ensure progress. As an example, the long message protocol of PM requires that the application receive and reply to a request to put or get a long message. This complicates the runtime environment, requiring a thread to process incoming requests, and significantly increases the latency required to initiate a long message protocol. The Portals message passing protocol does not require activity on the part of the application to ensure progress. We use the term “Application Bypass” to refer to this aspect of the Portals protocol.

2 An Overview of the Portals API

In this section, we give a conceptual overview of the Portals API. The goal is to provide a context for understanding the detailed description of the API presented in the next section.

2.1 Data Movement

A portal represents an opening in the address space of a process. Other processes can use a portal to read (get) or write (put) the memory associated with the portal. Every data movement operation involves two processes, the **initiator** and the **target**. The initiator is the process that initiates the data movement operation. The target is the process that responds to the operation by either accepting the data for a put operation, or replying with the data for a get operation.

In this discussion, activities attributed to a process may refer to activities that are actually performed by the process or *on behalf of the process*. The inclusiveness of our terminology is important in the context of *application bypass*. In particular, when we note that the target sends a reply in the case of a get operation, it is possible that reply will be generated by another component in the system, bypassing the application.

Figures 1 and 2 present graphical interpretations of the Portal data movement operations: put and get. In the case of a put operation, the initiator sends a put request message containing the data to the target. The target translates the portal addressing information in the request using its local portal structures. When the request has been processed, the target optionally sends an acknowledgement message.

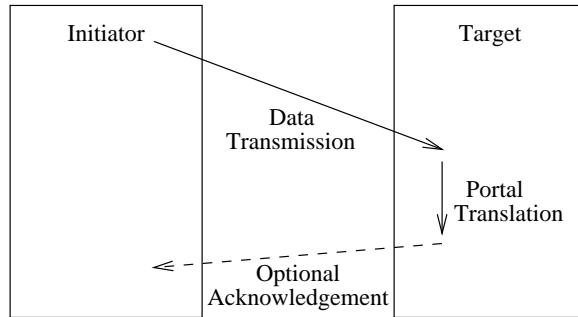

Figure 1: Portal Put (Send)

In the case of a get operation, the initiator sends a get request to the target. As with the put operation, the target translates the portal addressing information in the request using its local portal structures. Once it has translated the portal addressing information, the target sends a reply that includes the requested data.

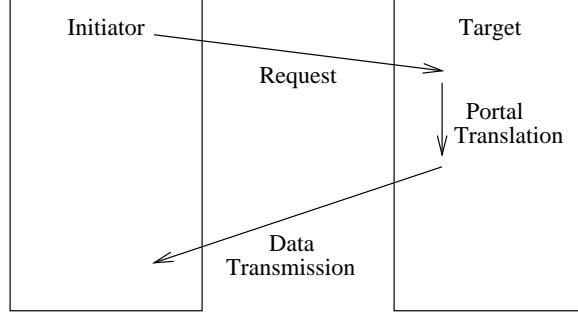

Figure 2: Portal Get

We should note that portal address translations are only performed on nodes that respond to operations initiated by other nodes. Acknowledgements and replies to get operations bypass the portals address translation structures.

2.2 Portal Addressing

One-sided data movement models (e.g., shmem [4], ST [12], MPI-2 [8]) typically use a triple to address memory on a remote node. This triple consists of a process id, memory buffer id, and offset. The process id identifies the target process, the memory buffer id specifies the region of memory to be used for the operation, and the offset specifies an offset within the memory buffer.

In addition to the standard address components (process id, memory buffer id, and offset), a portal address includes a set of match bits. This addressing model is appropriate for supporting one-sided operations as well as traditional two-sided message passing operations. Specifically, the Portals API provides the flexibility needed for an efficient implementation of MPI-1, which defines two-sided operations with one-sided semantics.

Figure 3 presents a graphical representation of the structures used by a target in the interpretation of a portal address. The process id is used to route the message to the appropriate node and is not reflected in this diagram. The memory buffer id, called the **portal id**, is used as an index into the portal table. Each element of the portals table identifies a match list. Each element of the match list specifies two bit patterns: a set of “don’t care” bits, and a set of “must match” bits. In addition to the two sets of match bits, each match list element has a list of memory descriptors. Each memory descriptor identifies a memory region and an optional event queue. The memory region specifies the memory to be used in the operation and the event queue is used to record information about these operations.

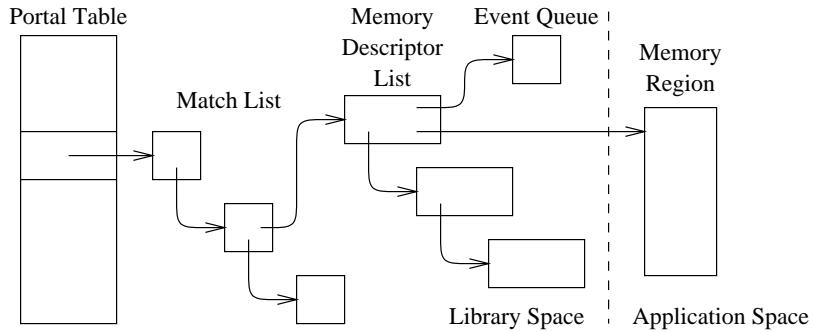

Figure 3: Portal Addressing Structures

Figure 4 illustrates the steps involved in translating a portal address, starting from the first element in a match list. If the match criteria specified in the match list entry are met and the first entry in the memory descriptor list accepts the operation¹, the operation (put or get) is performed using the memory region specified in the memory descriptor. (Note, while the match list is searched for a matching entry, only the first element in the memory descriptor list is

¹Memory descriptors can reject operations because the threshold has been exceeded or due to insufficient space in the memory region, see Section 3.7

considered for the operation.) If the memory descriptor specifies that it is to be unlinked after a successful operation, it is unlinked from the list of memory descriptors. Next, if the memory descriptor is unlinked and this empties the memory descriptor list, the match entry will also be unlinked if its unlink flag has been set. Finally, if there is an event queue specified in the memory descriptor, the operation is logged in the event queue.

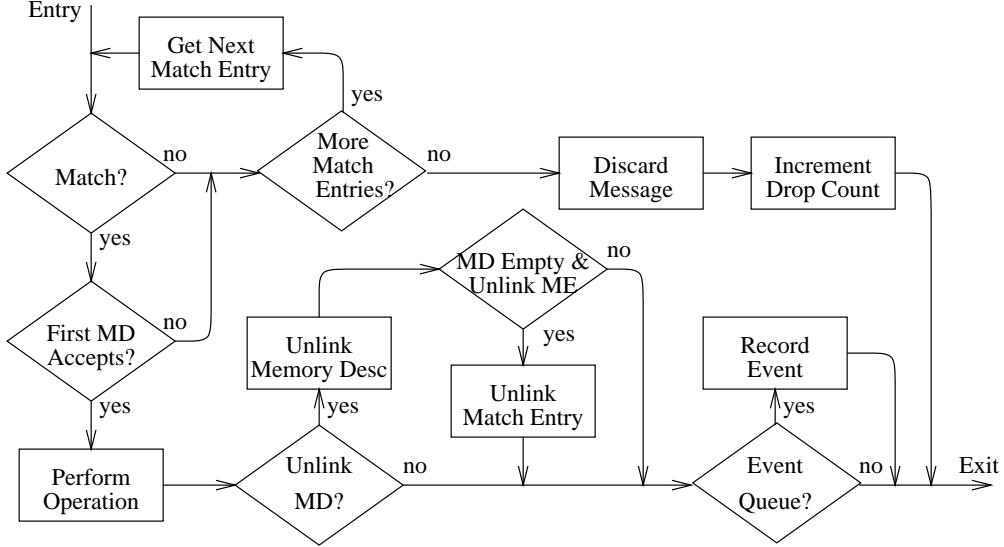

Figure 4: Portals Address Translation

If the match criteria specified in the match list entry are not met or the memory descriptor associated with the match list entry rejects the operation, the address translation continues with the next match list entry. If the end of the match list has been reached, the address translation is aborted and the incoming requested is discarded.

2.3 Access Control

A process can control access to its portals using an access control list. Each entry in the access control list specifies a process id, a user id, and a portal table index. The access control list is actually an array of entries. Each incoming request includes an index into the access control list (i.e., a “cookie” or hint). If the id of the process issuing the request doesn’t match the id specified in the access control list entry, the user id of the issuing process doesn’t match the user id specified in the entry, or the portal table index specified in the request doesn’t match the portal table index specified in the access control list entry, the request is rejected.

Process identifiers, user identifiers, and portal table indexes may include wildcard values to increase the flexibility of this mechanism. When the access control list is initialized, the entry with index zero enables access to all portals for all processes in the same application (and hence the same user id) and the entry with index one enables access to all portals for all system processes. The remaining entries are set to disable all other access.

Two aspects of this design merit further discussion. First, the model assumes that the information in a message header, the sender’s id and user id in particular, is trustworthy. In most contexts, we assume that the entity that constructs the header is trustworthy; however, using cryptographic techniques, we could easily devise a protocol that would ensure the authenticity of the sender.

Second, because the access check is performed by the receiver, it is possible that a malicious process will generate thousands of messages that will be denied by the receiver. This could saturate the network and/or the receiver, resulting in a *denial of service* attack. Moving the check to the sender using capabilities, would remove the potential for this form of attack. However, the solution introduces the complexities of capability management (exchange of capabilities, revocation, protections, etc).

3 The Portals API

3.1 Naming Conventions

The Portals API defines two types of entities: functions and types. Function always start with *Ptl* and use mixed upper and lower case. When used in the body of this report, function names appear in italic face, e.g., *PtlInit*. The functions associated with an object type will have names that start with *Ptl*, followed by the two letter object type code shown in Table 1. As an example, the function *PtlEQAlloc* allocates resources for an event queue.

Table 1: Object Type Codes

<i>xx</i>	Name	Section
EQ	Event Queue	3.8
MD	Memory Descriptor	3.7
ME	Match Entry	3.6
NI	Network Interface	3.5

Type names use lower case with underscores to separate words. Each type name starts with `ptl_` and ends with `_t`. When used in the body of this report, type names appear in a fixed font, e.g., `ptl_match_bits_t`.

Names for constants use upper case with underscores to separate words. Each constant name starts with `PTL_`. When used in the body of this report, type names appear in a fixed font, e.g., `PTL_OK`.

3.2 Base Types

The Portals API defines a variety of base types. These types represent a simple renaming of the base types provided by the C programming language. In most cases these new type names have been introduced to improve type safety and to avoid issues arising from differences in representation sizes (e.g., 16-bit or 32-bit integers).

3.2.1 Sizes

The type `ptl_size_t` is an unsigned integral type used for representing sizes.

3.2.2 Handles

Objects maintained by the API are accessed through handles. Handle types have names of the form `ptl_handle_xx_t`, where *xx* is one of the two letter object type codes shown in Table 1. For example, the type `ptl_handle_ni_t` is used for network interface handles.

Each type of object is given a unique handle type to enhance type checking. The type, `ptl_handle_any_t`, can be used when a generic handle is needed. Every handle value can be converted into a value of type `ptl_handle_any_t` without loss of information.

Handles are not simple values. Every portals object is associated with a specific network interface and an identifier for this interface (along with an object identifier) is part of the handle for the object.

3.2.3 Indexes

The types `ptl_pt_index_t` and `ptl_ac_index_t` are integral types used for representing portal table indexes and access control tables indexes, respectively.

3.2.4 Match Bits

The type `ptl_match_bits_t` is capable of holding unsigned 64-bit integer values.

3.2.5 Network Interfaces

The type `ptl_interface_t` is an integral type used for identifying different network interfaces. Users will need to consult the local documentation to determine appropriate values for the interfaces available. The special value `PTL_INTERFACE_DEFAULT` identifies the default interface.

3.2.6 Identifiers

The type `ptl_id_t` is an integral type used for representing group ids, node ids, process ids, and rank ids.

3.2.7 Status Registers

Each network interface maintains an array of status registers that can be accessed using the `PtlNISstatus` function (see Section 3.5.4). The type `ptl_sr_index_t` defines the types of indexes that can be used to access the status registers. The only index defined for all implementations is `PTL_SR_DROP_COUNT` which identifies the status register that counts the dropped requests for the interface. Other indexes (and registers) may be defined by the implementation.

The type `ptl_sr_value_t` defines the types of values held in status registers. This is a signed integer type. The size is implementation dependent, but must be at least 32 bits.

3.3 Initialization and Cleanup

The Portals API includes a function, `PtlInit`, to initialize the library and a function, `PtlFini`, to cleanup after the application is done using the library.

3.3.1 PtlInit

```
int PtlInit( void );
```

The `PtlInit` function initializes the Portals library. This function should be called by all processes in an application before calling any of the functions defined by the Portal API. This function should be called at least once during initialization by each process in a parallel job.

Return Codes

<code>PTL_OK</code>	Indicates success.
<code>PTL_FAIL</code>	Indicates an error during initialization.

Implementation Notes

This operation may be implemented as a collective operation involving all of the processes in a group.

3.3.2 PtlFini

```
void PtlFini( void );
```

The `PtlFini` function cleans up after the Portals library is no longer needed by a process. After this function is called, calls to any of the functions defined by the Portal API or use of the structures set up by the Portals API will result in undefined behavior. This function should be called once and only once during termination by each process in a parallel job. Typically, this function will be called in the exit sequence of each process.

3.4 Process Identification

Processes that use the Portals API, can be identified using a node id and process id. Every node in the computing system has a unique node identifier and every process running on a node has a unique process identifier. As such, any process in the computing system can be identified by its node id and process id. Processes can also be identified using a group id and rank id. When a portals job is loaded, it is given a unique group identifier. In addition, each process in the job is assigned a unique rank id starting at zero.

The Portals API defines a type, `ptl_process_id_t` for representing process ids using either or both of the schemes, a function, `PtlGetId`, which can be used to obtain the id of the current process, and a function, `PtlTransId`, to translate addresses between the two schemes.

3.4.1 The Process Id Type

```
typedef enum { PTL_ADDR_NID, PTL_ADDR_GID, PTL_ADDR_BOTH } ptl_addr_kind_t;

typedef struct {
    ptl_addr_kind_t addr_kind; /* kind of address pair */
    ptl_id_t        nid, pid;  /* node id, process id */
    ptl_id_t        gid, rid;  /* group id, rank id */
} ptl_process_id_t;
```

The `ptl_process_id_t` type uses a tag and up to four identifiers to represent a process id. Whenever a process id is filled in by the interface (e.g., by `PtlGetId` or when an event is recorded), the `addr_kind` member is set to `PTL_ADDR_BOTH`, and all four of the four remaining members will be set to the appropriate values. When a process id is passed to an operation in the Portals API (e.g., `PtlGetId` or `PtlGet`), the `addr_kind` member must be `PTL_ADDR_NID` or `PTL_ADDR_GID` and the `nid` and `pid` or `gid` and `rid` members must be filled in, respectively.

3.4.2 PtlGetId

```
int PtlGetId( ptl_handle_ni_t ni_handle,
               ptl_process_id_t* id,
               ptl_id_t* gsize );
```

Return Codes

<code>PTL_OK</code>	Indicates success.
<code>PTL_NOINIT</code>	Indicates that the Portals API has not been successfully initialized.
<code>PTL_SEGV</code>	Indicates that <code>id</code> or <code>gsize</code> is not a legal address.

Arguments

<code>handle</code>	<code>input</code>	A network interface handle.
<code>id</code>	<code>output</code>	On successful return, this location will hold the id for the calling process.
<code>gsize</code>	<code>output</code>	On successful return, this location will hold the number of processes in the process group for this process.

Implementation Notes

Notice that process identifiers are independent of the network interface(s) used by the process.

3.4.3 PtlTransId

```
int PtlTransId( ptl_handle_ni_t ni_handle,
                 ptl_process_id_t old_id,
                 ptl_process_id *new_id );
```

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_SEGV	Indicates that <code>id</code> is not a legal address.
PTL_ADDR_UNKNOWN	Indicates that the address could not be translated.

Arguments

<code>ni_handle</code>	input	A network interface handle.
<code>id</code>	input	The process address to be translated. This address should be expressed using <code>nid</code> , <code>pid</code> or <code>gid</code> , <code>rid</code> addressing, i.e., <code>addr_kind</code> should be <code>PTL_ADDR_NID</code> or <code>PTL_ADDR_GID</code> .
<code>new_id</code>	output	On successful return, this location will hold a process address with all four address members filled in, i.e., <code>addr_kind</code> will be <code>PTL_ADDR_BOTH</code> .

Implementation Notes

This operation should be implemented as a local operation. That is, the API should not query other nodes to determine the translation for a process address. As a minimum, the API should be able to translate any addresses for processes in the same group as the calling process. Other translations can be provided at the discretion of the implementor. For example, an implementation may maintain a cache of recent addresses that it has seen. (Every incoming message includes all four addresses for the sending process.)

3.5 Network Interfaces

The Portals API supports the use of multiple network interfaces. However, each interface is treated as an independent entity. Combining interfaces (e.g., “bonding” to create a higher bandwidth connection) must be implemented by the application or embedded in the underlying network. Interfaces are treated as independent entities to make it easier to cache information on individual network interface cards.

Once initialized, each interface provides a portal table, an access control table, and a collection of status registers. See Section 3.6 for a discussion of updating portal table entries using the *PtlMEAttach* function. See Section 3.9 for a discussion of the initialization and updating of entries in the access control table. See Section 3.5.4 for a discussion of the *PtlNISstatus* function which can be used to determine the value of a status register.

Every other type of Portal object (e.g., memory descriptor, event queue, or match entry) is associated with a specific network interface. The association to a network interface is established when the object is created and is encoded in the handle for the object.

Each network interface is initialized and shutdown independently. The initialization routine, *PtlNIInit*, returns a handle for an interface object which is used in all subsequent portal operations. The *PtlNIFini* function is used to shutdown an interface and release any resources that are associated with the interface.

The Portals API also defines the *PtlNISstatus* function to query the status registers for a network interface, the *PtlNIDist* function to determine the “distance” to another process, and the *PtlNIHandle* function to determine the network interface that an object is associated with.

3.5.1 PtlNIInit

```
int PtlNIInit( ptl_interface_t  interface,
                ptl_pt_index_t   ptl_size,
                ptl_ac_index_t   acl_size,
                ptl_handle_ni_t* handle );
```

The *PtlNIInit* function is used to initialize the Portals API for a network interface. This function must be called before any other operations that apply to the interface. It is not an error to initialize a network interface more than once in the same process. Calls to this function after the first successful call will continue to return a valid network interface handle.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INIT_DUP	Indicates a duplicate initialization of <code>interface</code> .
PTL_INIT_INV	Indicates that <code>interface</code> is not a valid network interface.
PTL_NOSPACE	Indicates that there is insufficient memory to initialize the interface.
PTL_INV_PSIZE	Indicates that <code>ptl_size</code> is invalid.
PTL_INV_ASIZE	Indicates that <code>acl_size</code> is invalid.
PTL_SEGV	Indicates that <code>handle</code> is not a legal address.

Arguments

<code>interface</code>	input	Identifies the network interface to be initialized. (See section 3.2.5 for a discussion of values used to identify network interfaces.)
<code>ptl_size</code>	input	Specifies the number of entries in the portal table for this interface.
<code>acl_size</code>	input	Specifies the size of the access control list for this interface. (See section 3.9 for more information about access control lists.)
<code>handle</code>	output	On successful return, this location will hold a handle for the interface.

Implementation Notes

The maximum number of portal table entries allowed by a specific interface is implementation dependent. Some portal table indexes may be reserved by the implementation. The initialization routine is a local operation and should not involve communication with any other nodes.

3.5.2 PtlNIFini

```
int PtlNIFini( ptl_handle_ni_t interface );
```

The *PtlNIFini* function is used to release the resources allocated for a network interface. Once the *PtlNIFini* operation has been started, the results of pending API operations (e.g., operations initiated by another thread) for this interface are undefined. Similarly, the effects of incoming operations (puts and gets) or return values (acknowledgements and replies) for this interface are undefined.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_NI	Indicates that <code>interface</code> is not a valid network interface handle.

Arguments

<code>interface</code>	input	A handle for the interface to shutdown.
------------------------	--------------	---

3.5.3 PtlNIBarrier

```
int PtlNIBarrier( ptl_handle_ni_t interface );
```

The *PtlNIBarrier* function blocks the calling process until all processes in the process group have invoked the *PtlNI-Barrier* function for the specified interface.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_NI	Indicates that <code>interface</code> is not a valid network interface handle.

Arguments

`interface` **input** A handle for the interface to use.

3.5.4 PtlNIStatus

```
int PtlNIStatus( ptl_handle_ni_t interface,
                  ptl_sr_index_t register,
                  ptl_sr_value_t* status );
```

The *PtlNIStatus* function returns the value of a status register for the specified interface. (See section 3.2.7 for more information on status register indexes and status register values.)

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_NI	Indicates that <code>interface</code> is not a valid network interface handle.
PTL_INV_SR_INDX	Indicates that <code>register</code> is not a valid status register.
PTL_SEGV	Indicates that <code>status</code> is not a legal address.

Arguments

`interface` **input** A handle for the interface to use.

`register` **input** An index for the status register to read.

`status` **output** On successful return, this location will hold the current value of the status register.

Implementation Notes

The only status register that must be defined is a drop count register (PTL_SR_DROP_COUNT). Implementations may define additional status registers. Identifiers for the indexes associated with these registers should start with the prefix `PTL_SR_`.

3.5.5 PtlNIDist

```
int PtlNIDist( ptl_handle_ni_t interface,
                ptl_process_id_t process,
                unsigned long* distance );
```

The *PtlNIDist* function returns the distance to another process using the specified interface. Distances are only defined relative to an interface. Distance comparisons between different interfaces on the same node may be meaningless.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_NI	Indicates that <code>interface</code> is not a valid network interface handle.
PTL_INV_PROC	Indicates that <code>process</code> is not a valid process identifier.
PTL_SEGV	Indicates that <code>distance</code> is not a legal address.

Arguments

interface	input	A handle for the interface to use.
process	input	An identifier for the process whose distance is being requested.
distance	output	On successful return, this location will hold the distance to the remote process.

Implementation Notes

This function should return a static measure of distance. Examples include minimum latency, the inverse of available bandwidth, or the number of switches between the two endpoints.

3.5.6 PtlNIHandle

```
int PtlNIHandle( ptl_handle_any_t handle,
                  ptl_handle_ni_t* interface );
```

The *PtlNIHandle* function returns a handle for the network interface that the object identified by *handle* is associated with. If the object identified by *handle* is a network interface, this function returns the same value it is passed.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_HANDLE	Indicates that <i>handle</i> is not a valid handle.
PTL_SEGV	Indicates that <i>interface</i> is not a legal address.

Arguments

handle	input	A handle for the object.
interface	output	On successful return, this location will hold a handle for the network interface associated with <i>handle</i> .

Implementation Notes

Every handle should encode the network interface and the object id relative to this handle. Both are presumably encoded using integer values.

3.6 Match Entries and Match Lists

A match list is a chain of match entries. Each match entry includes a list of memory descriptors and a set of match criteria. The match criteria can be used to reject incoming requests based on process id and/or the match bits provided in the request. A match list is created using the *PtlMEAttach* function which creates a match list consisting of a single match entry, attaches the match list to the specified portal index, and returns a handle for the match entry. Match entries can be dynamically inserted and removed from a match list using the *PtlMEInsert* and *PtlMEUnlink* functions.

3.6.1 PtlMEAttach

```
typedef enum { PTL_RETAIN, PTL_UNLINK } ptl_unlink_t;

int PtlMEAttach( ptl_handle_ni_t interface,
                  ptl_pt_index_t index,
                  ptl_process_id_t matchid,
                  ptl_match_bits_t match_bits,
                  ptl_match_bits_t ignorebits,
                  ptl_unlink_t unlink,
                  ptl_handle_me_t* handle );
```

Values of the type `ptl_unlink_t` are used to control whether an item is unlinked from a list. The value `PTL_UNLINK` enables unlinking. The value `PTL_RETAIN` disables unlinking.

The `PtlMEAttach` function creates a match list consisting of a single entry and attaches this list to the portal table for `interface`. If the portal table already has a match list attached to the specified index, the existing list (including any attached memory descriptor lists) must first be unlinked.

Return Codes

<code>PTL_OK</code>	Indicates success.
<code>PTL_NOINIT</code>	Indicates that the Portals API has not been successfully initialized.
<code>PTL_INUSE</code>	Indicates that the portal table index already has a match entry attached.
<code>PTL_INV_PTINDEX</code>	Indicates that <code>index</code> is not a valid portal table index.
<code>PTL_INV_PROC</code>	Indicates that <code>matchid</code> is not a valid process identifier.
<code>PTL_NOSPACE</code>	Indicates that there is insufficient memory to allocate the match entry.
<code>PTL_SEGV</code>	Indicates that <code>handle</code> is not a legal address.

Arguments

<code>interface</code>	<code>input</code>	A handle for the interface to use.
<code>index</code>	<code>input</code>	The portal table index where the match list should be attached.
<code>matchid</code>	<code>input</code>	Specifies the match criteria for the process id of the requestor. The constant <code>PTL_ID_ANY</code> can be used to wildcard any of the ids in the <code>ptl_process_id_t</code> structure.
<code>match_bits</code> ,	<code>input</code>	Specify the match criteria to apply to the match bits in the incoming request. The <code>ignorebits</code> are used to mask out insignificant bits in the incoming match bits. The resulting bits are then compared to the match entry's match bits to determine if the incoming request meets the match criteria.
<code>ig-</code>		
<code>norebits</code>		
<code>unlink</code>	<code>input</code>	Indicates the match list entry should be unlinked when the last memory descriptor associated with this match entry is unlinked. (Note, the check for unlinking a match entry only occurs when a memory descriptor is unlinked and this leaves the memory descriptor list empty.)
<code>handle</code>	<code>output</code>	On successful return, this location will hold a handle for the newly created match entry.

3.6.2 PtlMEInsert

```
typedef enum { PTL_INS_BEFORE, PTL_INS_AFTER } ptl_ins_pos_t;

int PtlMEInsert( ptl_handle_me_t current,
                  ptl_process_id_t matchid,
                  ptl_match_bits_t match_bits,
                  ptl_match_bits_t ignorebits,
                  ptl_unlink_t      unlink,
                  ptl_ins_pos_t     position,
                  ptl_handle_me_t* handle );
```

Values of the type `ptl_ins_pos_t` are used to control where a new item is inserted in a list. The value `PTL_INS_BEFORE` is used to insert the new item before the current item. The value `PTL_INS_AFTER` is used to insert the new item after the current item.

The `PtlMEInsert` function creates a new match entry and inserts this entry into the match list containing `current`.

Return Codes

<code>PTL_OK</code>	Indicates success.
---------------------	--------------------

PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_PROC	Indicates that <code>matchid</code> is not a valid process identifier.
PTL_INV_ME	Indicates that <code>current</code> is not a valid match entry handle.
PTL_ML_TOOLONG	Indicates that the resulting match list is too long. The maximum length for a match list is defined by the interface.
PTL_NOSPACE	Indicates that there is insufficient memory to allocate the match entry.
PTL_SEGV	Indicates that <code>handle</code> is not a legal address.

Arguments

<code>current</code>	input	A handle for a match entry. The new match entry will be inserted immediately before or immediately after this match entry.
<code>matchid,</code>	input	See the discussion for <i>PtlMEAttach</i> .
<code>match_bits,</code>		
<code>ig-</code>		
<code>norebits,</code>		
<code>unlink</code>		
<code>position</code>	input	Indicates whether the new match entry should be inserted before or after the <code>current</code> entry.
<code>handle</code>	input	See the discussion for <i>PtlMEAttach</i> .

3.6.3 PtlMEUnlink

```
int PtlMEUnlink( ptl_handle_me_t entry );
```

The *PtlMEUnlink* function can be used to unlink a match entry from a match list. This operation also releases any resources associated with the match entry (including the list of associated memory descriptors). It is an error to use the match entry handle after calling *PtlMEUnlink*.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_ME	Indicates that <code>entry</code> is not a valid match entry handle.

Arguments

<code>entry</code>	input	A handle for the match entry to be unlinked.
--------------------	--------------	--

3.7 Memory Descriptors

A memory descriptor contains information about a region of an application process' memory and an event queue where information about the operations performed on the memory descriptor are recorded. The Portals API provides three operations to create memory descriptors: *PtlMDAttach*, *PtlMEInsert*, and *PtlMEBind*; an operation to update a memory descriptor, *PtlMDUpdate*; and an operation to unlink and release the resources associated with a memory descriptor, *PtlMDUnlink*.

3.7.1 The Memory Descriptor Type

```
typedef struct {
    void*           start;
    ptl_size_t      length;
    int             threshold;
    unsigned int    options;
    void*           user_ptr;
```

```

    ptl_handle_eq_t eventq;
} ptl_md_t;

```

The `ptl_md_t` type defines the application view of a memory descriptor. Values of this type are used to initialize and update the memory descriptors.

Members

<code>start, length</code>	Specify the memory region associated with the memory descriptor. The <code>start</code> member specifies the starting address for the memory region and the <code>length</code> member specifies the length of the region. The <code>start</code> member can be <code>NULL</code> provided that the <code>length</code> member is zero. (Zero length buffers are useful to record events.) There are no alignment restrictions on the starting address or the length of the region; although, unaligned messages may be slower (i.e., lower bandwidth and/or longer latency) on some implementations.
<code>threshold</code>	Specifies the maximum number of operations that can be performed on the memory descriptor. An operation is any action that could possibly generate an event (see Section sec:ek-type for the different types of events). In the usual case, the threshold value is decremented for each operation on the memory descriptor. When the threshold value is zero, the memory descriptor is <i>inactive</i> , and does not respond to operations. A memory descriptor can have an initial threshold value of zero to allow for manipulation of an inactive memory descriptor by the local process. A threshold value of <code>PTL_MD_THRESH_INF</code> indicates that there is no bound on the number of operations that may be applied to a memory descriptor. Note that local operations (e.g., <i>PtlMDUpdate</i>) are not applied to the threshold count.
<code>options</code>	Specifies the behavior of the memory descriptor. There are five options that can be selected: enable put operations (yes or no), enable get operations (yes or no), offset management (local or remote), message truncation (yes or no), and acknowledgement (yes or no). Values for this argument can be constructed using a bitwise or of the following values:
<code>PTL_MD_OP_PUT</code>	Specifies that the memory descriptor will respond to <i>put</i> operations. By default, memory descriptors reject <i>put</i> operations.
<code>PTL_MD_OP_GET</code>	Specifies that the memory descriptor will respond to <i>get</i> operations. By default, memory descriptors reject <i>get</i> operations.
<code>PTL_MD_MANAGE_REMOTE</code>	Specifies that the offset used in accessing the memory region is provided by the incoming request. By default, the offset is maintained locally. When the offset is maintained locally, the offset is incremented by the length of the request so that the next operation will access the next part of the memory region.
<code>PTL_MD_TRUNCATE</code>	Specifies that the length provided in the incoming request can be reduced to match the memory available in the region. (The memory available in a memory region is determined by subtracting the offset from the length of the memory region.) By default, if the length in the incoming operation is greater than the amount of memory available, the operation is rejected.
<code>PTL_MD_ACK_DISABLE</code>	Specifies that an acknowledgement should <i>not</i> be sent for incoming <i>put</i> operations, even if requested. By default, acknowledgements are sent for <i>put</i> operations that request an acknowledgement. Acknowledgements are never sent for <i>get</i> operations. The value sent in the reply serves as an implicit acknowledgement.

Note: It is not considered an error to have a memory descriptor that does not respond to

<code>user_ptr</code>	either <i>put</i> or <i>get</i> operations: Every memory descriptor responds to <i>reply</i> operations. Nor is it considered an error to have a memory descriptor that responds to both <i>put</i> and <i>get</i> operations.
	A user-specified value that is associated with the memory descriptor. The value does not need to be a pointer, but must fit in the space used by a pointer. This value (along with other values) is recorded in events associated with operations on this memory descriptor. ²
<code>eventq</code>	A handle for the event queue used to log the operations performed on the memory region. If this argument is <code>PTL_EQ_NONE</code> , operations performed on this memory descriptor are not logged.

3.7.2 PtlMDAttach

```
int PtlMDAttach( ptl_handle_me_t  match,
                  ptl_md_t          mem_desc,
                  ptl_unlink_t       unlink,
                  ptl_handle_md_t*  handle );
```

The *PtlMDAttach* operation is used to create a memory descriptor list consisting of a single memory descriptor and attach this list to a match entry. If this match entry already has a list of memory descriptors, the existing memory descriptors must first be unlinked.

Return Codes

<code>PTL_OK</code>	Indicates success.
<code>PTL_NOINIT</code>	Indicates that the Portals API has not been successfully initialized.
<code>PTL_INUSE</code>	Indicates that <code>match</code> already has a memory descriptor attached.
<code>PTL_INV_ME</code>	Indicates that <code>match</code> is not a valid match entry handle.
<code>PTL_ILL_MD</code>	Indicates that <code>mem_desc</code> is not a legal memory descriptor. This may happen because the memory region defined in <code>mem_desc</code> is invalid or because the network interface associated with the <code>eventq</code> in <code>mem_desc</code> is not the same as the network interface associated with <code>match</code> .
<code>PTL_NOSPACE</code>	Indicates that there is insufficient memory to allocate the memory descriptor.
<code>PTL_SEGV</code>	Indicates that <code>handle</code> is not a legal address.

Arguments

<code>match</code>	input	A handle for the match entry that the memory descriptor will be associated with.
<code>mem_desc</code>	input	Provides initial values for the application visible parts of a memory descriptor. Other than its use for initialization, there is no linkage between this structure and the memory descriptor maintained by the API.
<code>unlink</code>	input	A flag to indicate whether the memory descriptor is unlinked when its threshold drops to zero. (Note, the check for unlinking a memory descriptor only occurs when the threshold transitions from one to zero when responding to an operation. If the threshold is set to zero during initialization or using <i>PtlMDUpdate</i> , the memory descriptor is not unlinked.)
<code>handle</code>	output	On successful return, this location will hold a handle for the newly created memory descriptor. The <code>handle</code> argument can be <code>NULL</code> , in which case the handle will not be returned ³ .

²Tying the memory descriptor to a user-defined value can be useful when multiple memory descriptor share the same event queue or when the memory descriptor needs to be associated with a data structure maintained by the application. For example, an MPI implementation can set the `user_ptr` argument to the value of an MPI Request. This direct association allows for processing of memory descriptor's by the MPI implementation without a table lookup or a search for the appropriate MPI Request.

3.7.3 PtlMDInsert

```
int PtlMDInsert( ptl_handle_md_t  current,
                  ptl_md_t          mem_desc,
                  ptl_unlink_t       unlink,
                  ptl_ins_pos_t      position,
                  ptl_handle_md_t*   handle );
```

The *PtlMDInsert* creates a new memory descriptor and links it into the list containing *current*.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_ILL_MD	Indicates that <i>mem_desc</i> is not a legal memory descriptor (e.g., the memory region specified by the memory descriptor may be invalid).
PTL_INV_MD	Indicates that <i>current</i> is not a valid memory descriptor handle.
PTL_NOSPACE	Indicates that there is insufficient memory to allocate the memory descriptor.
PTL_SEGV	Indicates that <i>handle</i> is not a legal address.

Arguments

current	input	A handle for a memory descriptor. The new memory descriptor will be inserted immediately before or immediately after this memory descriptor.
mem_desc ,	input	See the discussion for <i>PtlMDAttach</i> .
unlink		
position	input	Indicates whether the new memory descriptor should be inserted before or after the <i>current</i> entry.
handle	output	See the discussion for <i>PtlMDAttach</i> .

3.7.4 PtlMDBind

```
int PtlMDBind( ptl_handle_ni_t  interface,
                ptl_md_t          mem_desc,
                ptl_handle_md_t*   handle );
```

The *PtlMDBind* operation is used to create a “free floating” memory descriptor, i.e., a memory descriptor that is not part of the memory descriptor list for a match entry.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_NI	Indicates that <i>interface</i> is not a valid match entry handle.
PTL_ILL_MD	Indicates that <i>mem_desc</i> is not a legal memory descriptor. This may happen because the memory region defined in <i>mem_desc</i> is invalid or because the network interface associated with the <i>eventq</i> in <i>mem_desc</i> is not the same as the network interface, <i>interface</i> .
PTL_NOSPACE	Indicates that there is insufficient memory to allocate the memory descriptor.
PTL_SEGV	Indicates that <i>handle</i> is not a legal address.

Arguments

interface	input	A handle for the network interface that the memory descriptor will be associated with.
mem_desc	input	Provides initial values for the application visible parts of a memory descriptor. Other than its use for initialization, there is no linkage between this structure and the memory descriptor maintained by the API.
handle	output	On successful return, this location will hold a handle for the newly created memory descriptor. The handle argument must be a valid address and cannot be NULL.

3.7.5 PtlMDUnlink

```
int PtlMDUnlink( ptl_handle_md_t mem_desc );
```

The *PtlMDUnlink* function unlinks the memory descriptor from any memory descriptor list it may be linked to and releases the resources associated with a memory descriptor. (This function does not free the memory region associated with the memory descriptor.)

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_MD	Indicates that mem_desc is not a valid memory descriptor handle.

Arguments

mem_desc	input	A handle for the memory descriptor to be released.
----------	--------------	--

3.7.6 PtlMDUpdate

```
int PtlMDUpdate( ptl_handle_md_t mem_desc,
                  ptl_md_t*          old,
                  ptl_md_t*          new,
                  ptl_handle_eq_t    testq );
```

The *PtlMDUpdate* function provides a conditional, atomic update operation for memory descriptors. If old is not NULL, the current value of the memory descriptor identified by mem_desc is recorded in the location identified by old. If new is not NULL the memory descriptor identified by handle will be updated to reflect the values in the structure pointed to by new if testq has the value PTL_EQ_NONE or if the event queue identified by testq is empty.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_NOUPDATE	Indicates that the update was not performed because testq was not empty.
PTL_INV_MD	Indicates that mem_desc is not a valid memory descriptor handle.
PTL_ILL_MD	Indicates that the value pointed to by new is not a legal memory descriptor (e.g., the memory region specified by the memory descriptor may be invalid).
PTL_INV_EQ	Indicates that testq is not a valid event queue handle.
PTL_SEGV	Indicates that new or old is not a legal address.

Arguments

mem_desc	input	A handle for the memory descriptor to update.
old	output	If <code>old</code> is not the value <code>NULL</code> , the current value of the memory descriptor will be stored in the location identified by <code>old</code> .
new	input	If <code>new</code> is not the value <code>NULL</code> , this argument provides the new values for the memory descriptor, if the update is performed.
testq	input	A handle for an event queue used to predicate the update. If <code>testq</code> is equal to <code>PTL_EQ_NONE</code> , the update is performed unconditionally. Otherwise, the update is performed if and only if <code>testq</code> is empty. If the update is not performed, the function returns the value <code>PTL_NOUPDATE</code> . (Note, the <code>testq</code> argument does not need to be the same as the event queue associated with the memory descriptor.)

The conditional update can be used to ensure that the memory descriptor has not changed between the time it was examined and the time it is updated. In particular, it is needed to support an MPI implementation where the activity of searching an unexpected message queue and posting a receive must be atomic.

3.8 Events and Event Queues

Event queues are used to log operations performed on memory descriptors. They can also be used to hold acknowledgements for completed *put* operations and to note when the data specified in a *put* operation has been sent (i.e., when it is safe to reuse the buffer that holds this data). Multiple memory descriptors can share a single event queue.

In addition to the `ptl_handle_eq_t` type, the Portals API defines two types associated with events: The `ptl_event_kind_t` type defines the kinds of events that can be stored in an event queue. The `ptl_event_t` type defines a structure that holds the information associated with an event.

The Portals API also provides five functions for dealing with event queues: The `PtlEQAlloc` function is used to allocate the API resources needed for an event queue, the `PtlEQFree` function is used to release these resources, the `PtlEQCount` function can be used to obtain the number of events in an event queue, the `PtlEQGet` function can be used to get the next event from an event queue, and the `PtlEQWait` function can be used to block a process (or thread) until an event queue has at least one event.

3.8.1 Kinds of Events

```
typedef enum {
    PTL_EVENT_GET,
    PTL_EVENT_PUT,
    PTL_EVENT_REPLY,
    PTL_EVENT_ACK,
    PTL_EVENT_SENT
} ptl_event_kind_t;
```

The Portals API defines five types of events that can be logged in an event queue:

<code>PTL_EVENT_GET</code>	A remote <i>get</i> operation was performed on the memory descriptor. This event is logged after the reply has been sent by the local node. As such, the process could free the memory descriptor once it sees this event.
<code>PTL_EVENT_PUT</code>	A remote <i>put</i> operation was performed on the memory descriptor. This event is logged after the data (if any) is written into the memory descriptor and after the acknowledgement (if any) has been sent.
<code>PTL_EVENT_REPLY</code>	A <i>reply</i> has been received for the memory descriptor. This event is logged after the data (if any) from the reply has been written into the memory descriptor.
<code>PTL_EVENT_ACK</code>	An <i>acknowledgement</i> was received. This event is logged when the acknowledgement is received
<code>PTL_EVENT_SENT</code>	An outgoing buffer was sent (see Section 3.10.1). This event is logged after the entire buffer has been sent and it is safe for the application to reuse the buffer.

3.8.2 The Event Type

```
typedef struct {
    ptl_event_kind_t      type;
    unsigned int           sequence;
    ptl_process_id_t      initiator;
    ptl_pt_index_t        portal;
    ptl_match_bits_t      match_bits;
    ptl_size_t             rlength;
    ptl_size_t             mlength;
    ptl_size_t             offset;
    ptl_md_t               mem_desc;
    ptl_hdr_data_t        hdr_data;
} ptl_event_t;
```

An event structure includes the following members:

type	Indicates the type of operation that generated the event.
sequence	The sequence number of the event.
initiator	The id of the initiator (group id, rank id).
portal	The portal table index specified in the request.
match_bits	A copy of the match bits specified in the request. See section 3.6 for more information on match bits.
rlength	The length (in bytes) specified in the request.
mlength	The length (in bytes) of the data that was manipulated by the operation. For truncated operations, the manipulated length will be the number of bytes specified by the memory descriptor (possibly with an offset) operation. For all other operations, the manipulated length will be the length of the requested operation.
offset	Is the displacement (in bytes) into the memory region that the operation used. The offset can be determined by the operation (see Section 3.10) for a remote managed memory descriptor, or by the local memory descriptor (see Section 3.7).
mem_desc	Is a copy of the memory descriptor immediately after the event has been processed.
hdr_data	64 bits of out-of-band user data (see Section 3.10.1).

3.8.3 PtlEQAlloc

```
int PtlEQAlloc( ptl_handle_ni_t  interface,
                 ptl_size_t          count,
                 ptl_handle_eq_t*   handle );
```

The *PtlEQAlloc* function is used to build an event queue.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_NI	Indicates that <i>interface</i> is not a valid network interface handle.
PTL_NOSPACE	Indicates that there is insufficient memory to allocate the event queue.
PTL_SEGV	Indicates that <i>handle</i> is not a legal address.

Arguments

interface	input	A handle for the interface that the event queue will be associated with.
count	input	The number of events that can be stored in the event queue.
handle	output	On successful return, this location will hold a handle for the newly created event queue.

3.8.4 PtlEQFree

```
int PtlEQFree( ptl_handle_eq_t eventq );
```

The *PtlEQFree* function releases the resources associated with an event queue. This function does not free the memory region associated with the event queue. It is up to the user to insure that no memory descriptors are associated with the event queue once it is freed.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_EQ	Indicates that <code>eventq</code> is not a valid event queue handle.

Arguments

`eventq` **input** A handle for the event queue to be released.

3.8.5 PtlEQCount

```
int PltEQCount( ptl_handle_eq_t eventq,
                  ptl_size_t*      count );
```

The *PTLEQCount* function can be used to discover the number events in an event queue.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_EQ	Indicates that <code>eventq</code> is not a valid event queue handle.
PTL_SEGV	Indicates that <code>count</code> is not a legal address.

Arguments

`eventq` **input** A handle for the event queue.
`count` **output** On successful return, this location will hold the number of events in the event queue.

3.8.6 PtlEQGet

```
int PltEQGet( ptl_handle_eq_t eventq,
               ptl_event_t*    event );
```

The *PTLEQGet* function is a nonblocking function that can be used to get the next event in an event queue. The event is removed from the queue.

Return Codes

PTL_OK	Indicates success.
PTL_EQ_DROPPED	Indicates success (i.e., an event is returned) and that at least one event between this event and the last event obtained (using <i>PtlEQGet</i> or <i>PtlEQWait</i>) from this event queue has been dropped due to limited space in the event queue.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_EQ_EMPTY	Indicates that <code>eventq</code> is empty.
PTL_INV_EQ	Indicates that <code>eventq</code> is not a valid event queue handle.
PTL_SEGV	Indicates that <code>event</code> is not a legal address.

Arguments

eventq	input	A handle for the event queue.
event	output	On successful return, this location will hold the values associated with the next event in the event queue.

3.8.7 PtlEQWait

```
int PtlEQWait( ptl_handle_eq_t eventq,
                ptl_event_t*      event );
```

The *PtlEQWait* function can be used to block the calling process (thread) until there is an event in an event queue. This function also returns the next event in the event queue and removes this event from the queue. This is the only blocking operation in the Portals 3.0 API.

Return Codes

PTL_OK	Indicates success.
PTL_EQ_DROPPED	Indicates success (i.e., an event is returned) and that at least one event between this event and the last event obtained (using <i>PtlEQGet</i> or <i>PtlEQWait</i>) from this event queue has been dropped due to limited space in the event queue.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_EQ	Indicates that <i>eventq</i> is not a valid event queue handle.
PTL_SEGV	Indicates that <i>event</i> is not a legal address. queue handle.

Arguments

eventq	input	A handle for the event queue to wait on. The calling process (thread) will be blocked until <i>eventq</i> is not empty.
event	output	On successful return, this location will hold the values associated with the next event in the event queue.

3.9 The Access Control Table

Processes can use the access control table to control which processes and/or which users are allowed to perform operations on portal table entries. Each communication interface has a portal table and an access control table. The access control table for the default interface contains an entry at index zero that allows all members of the same group (and hence user) to communicate. Entries in the access control table can be manipulated using the *PtlACEntry* function.

3.9.1 PtlACEntry

```
int PtlACEntry( ptl_handle_ni_t interface,
                 ptl_ac_index_t   index,
                 ptl_processid_t  matchid,
                 uid_t            uid,
                 ptl_pt_index_t   portal );
```

The *PtlACEntry* function can be used to update an entry in the access control table for an interface.

Return Codes

PTL_OK	Indicates success.
PTL_NOINIT	Indicates that the Portals API has not been successfully initialized.
PTL_INV_NI	Indicates that <i>interface</i> is not a valid network interface handle.

`PTL_AC_INV_INDEX` Indicates that `index` is not a valid access control table index.

`PTL_INV_PROC` Indicates that `matchid` is not a valid process identifier.

`PTL_PT_INV_INDEX` Indicates that `portal` is not a valid portal table index.

Arguments

interface	input	Identifies the interface to use.
index	input	The index of the entry in the access control table to update.
matchid	input	Identifies the process(es) that are allowed to perform operations. The value <code>PTL_ID_ANY</code> can be used to wildcard either or both components of the process identifier.
uid	input	Identifies the user that is allowed to perform operations. The value <code>PTL_UID_ANY</code> can be used to specify any user.
portal	input	Identifies the portal index(es) that can be used. The value <code>PTL_PT_INDEX_ANY</code> can be used to wildcard the portal index.

Restricting access based on user ID may be desirable when a process needs to accept requests from a process that will be created sometime in the future. The exact location of this process cannot be known, but it is likely that the owner of that process is known ahead of time. For example, the MPI library may set up some portals that expose the state of MPI communications. At some later point in time, the user may run an application that reads this information. The exact location of the inspecting application is not known when the MPI job is run, but it will allow itself to be inspected only by the original owner of the job.

3.10 Data Movement Operations

The Portals API provides two data movement operations: `PtlPut` and `PtlGet`.

3.10.1 PtlPut

```
typedef enum { PTL_ACK_REQ, PTL_NOACK_REQ } ptl_ack_req_t;

int PtlPut( ptl_handle_md_t mem_desc,
            ptl_ack_req_t ack_req,
            ptl_process_id_t target,
            ptl_pt_index_t portal,
            ptl_ac_index_t cookie,
            ptl_match_bits_t match_bits,
            ptl_size_t offset,
            ptl_hdr_data_t hdr_data );
```

Values of the type `ptl_ack_req_t` are used to control whether an acknowledgement should be sent when the operation completes (i.e., when the data has been written to a memory descriptor of the `target` process). The value `PTL_ACK_REQ` requests an acknowledgement, the value `PTL_NOACK_REQ` requests that no acknowledgement should be generated.

The `PtlPut` function initiates an asynchronous put operation. There are two significant events associated with a put operation: completion of the send by the local node (`PTL_EVENT_SENT`) and the receipt of an acknowledgement (`PTL_EVENT_ACK`) indicating that the operation was accepted by the target. These events will be logged in the event queue associated with the memory descriptor (`mem_desc`) used in the put operation. Using a memory descriptor that does not have an associated event queue results in these events being discarded. In this case, the application must have another mechanism (e.g., a higher level protocol) for determining when it is safe to modify the memory region associated with the memory descriptor.

Return Codes

`PTL_OK` Indicates success.

`PTL_NOINIT` Indicates that the Portals API has not been successfully initialized.

<code>PTL_INV_MD</code>	Indicates that <code>mem_desc</code> is not a valid memory descriptor.
<code>PTL_INV_PROC</code>	Indicates that <code>target</code> is not a valid process id.

Arguments

<code>mem_desc</code>	input	A handle for the memory descriptor that describes the memory to be sent. If the memory descriptor has an event queue associated with it, it will be used to record an event when the message has been sent (<code>PTL_EVENT_SENT</code>).
<code>ack_req</code>	input	Controls whether an acknowledgement event is requested. Acknowledgements are only sent when they are requested by the initiating process and the memory descriptor has an event queue and the target memory descriptor enables them.
<code>target</code>	input	A process id for the target process.
<code>portal</code>	input	The index in the remote portal table.
<code>cookie</code>	input	The index into the access control table of the target process.
<code>match_bits</code>	input	The match bits to use for message selection at the target process.
<code>offset</code>	input	The offset into the target memory descriptor (only used when the target memory descriptor has the <code>PTL_MD_MANAGE_REMOTE</code> option set).
<code>hdr_data</code>	input	64 bits of user data that can be included in message header. This data is written to an event queue entry at the target if an event queue is present on the matching memory descriptor.

3.10.2 `PtlGet`

```
int PtlGet( ptl_handle_md_t mem_desc,
            ptl_process_id_t target,
            ptl_pt_index_t portal,
            ptl_ac_index_t cookie,
            ptl_match_bits_t match_bits,
            ptl_size_t         offset );
```

The `PtlGet` function initiates a remote read operation.

Return Codes

<code>PTL_OK</code>	Indicates success.
<code>PTL_NOINIT</code>	Indicates that the Portals API has not been successfully initialized.
<code>PTL_INV_MD</code>	Indicates that <code>mem_desc</code> is not a valid memory descriptor.
<code>PTL_INV_PROC</code>	Indicates that <code>target</code> is not a valid process id.

Arguments

<code>mem_desc</code>	input	A handle for the memory descriptor that describes the memory into which the requested data will be received. The memory descriptor can have an event queue associated with it to record events, such as when the message has been received (<code>PTL_EVENT_REPLY</code>).
<code>target</code>	input	A process id for the target process.
<code>portal</code>	input	The index in the remote portal table.
<code>cookie</code>	input	The index into the access control table of the target process.
<code>match_bits</code>	input	The match bits to use for message selection at the target process.
<code>offset</code>	input	The offset into the target memory descriptor (ignored unless the target memory descriptor has the <code>PTL_MD_MANAGE_REMOTE</code> option set).

3.11 Summary

We conclude this section by summarizing the names introduced by the Portals 3.0 API. We start by summarizing the names of the types introduced by the API. This is followed by a summary of the functions introduced by the API. Which is followed by a summary of the function return codes. Finally, we conclude with a summary of the other constant values introduced by the API.

Table 2 presents a summary of the types defined by the Portals API. The first column in this table gives the type name, the second column gives a brief description of the type, the third column identifies the section where the type is defined, and the fourth column lists the functions that have arguments of this type.

Table 2: Types Defined by the Portals 3.0 API

Name	Meaning	Section	Functions
<code>ptl_ac_index_t</code>	indexes for an access control table	3.2.3	<code>PtlACEntry, PtlPut, PtlGet</code>
<code>ptl_ack_req_t</code>	acknowledgement request types	3.10.1	<code>PtlPut</code>
<code>ptl_addr_kind_t</code>	kinds of process addresses (nid, pid or gid, rid)	3.4.1	
<code>ptl_event_kind_t</code>	kinds of events (get, put, reply, etc.)	3.8.1	<code>PtlGetId</code>
<code>ptl_event_t</code>	information about events	3.8.2	<code>PtlEQGet</code>
<code>ptl_handle_any_t</code>	handles for any object	3.2.2	<code>PtlNIHandle</code>
<code>ptl_handle_eq_t</code>	handles for event queues	3.2.2	<code>PtlEQAlloc, PtlEQFree, PtlEQCount, PtlEQGet, PtlEQWait, PtlMDUpdate</code>
<code>ptl_handle_md_t</code>	handles for memory descriptors	3.2.2	<code>PtlMDAlloc, PtlMDUnlink, PtlMDUpdate, PtlMEAttach, PtlMEInsert, PtlPut, PtlGet</code>
<code>ptl_handle_me_t</code>	handles for match entries	3.2.2	<code>PtlMEAttach, PtlMEInsert, PtlMEUnlink</code>
<code>ptl_handle_ni_t</code>	handles for network interfaces	3.2.2	<code>PtlNIIInit, PtlNIFini, PtlNIStatus, PtlNIDist, PtlEQAlloc, PtlACEntry, PtlPut, PtlGet</code>
<code>ptl_id_t</code>	identifiers (nid, pid, gid, rid)	3.2.6	
<code>ptl_ins_pos_t</code>	insertion position (before or after)	3.6.2	<code>PtlMeInsert, PtlMDInsert</code>
<code>ptl_interface_t</code>	identifiers for network interfaces	3.2.5	<code>PtlNIIInit</code>
<code>ptl_match_bits_t</code>	match (and ignore) bits	3.2.4	<code>PtlMEAttach, PtlMEInsert, PtlPut, PtlGet</code>
<code>ptl_md_t</code>	memory descriptors	3.7.1	<code>PtlMDAttach, PtlMDInsert, PtlMDUpdate</code>
<code>ptl_process_id_t</code>	process identifiers	3.4.1	<code>PtlGetId, PtlNIDist, PtlMEAttach, PtlACEntry, PtlPut, PtlGet</code>
<code>ptl_pt_index_t</code>	indexes for portal tables	3.2.3	<code>PtlMEAttach, PtlACEntry</code>
<code>ptl_size_t</code>	sizes	3.2.1	<code>PtlEQAlloc, PtlEQCount, PtlPut, PtlGet</code>
<code>ptl_sr_index_t</code>	indexes for status registers	3.2.7	<code>PtlNIStatus</code>
<code>ptl_sr_value_t</code>	values in status registers	3.2.7	<code>PtlNIStatus</code>
<code>ptl_unlink_t</code>	unlink options	3.6.1	<code>PtlMEAttach, PtlMEInsert, PtlMDAttach, PtlMDInsert</code>

Table 3 presents a summary of the functions defined by the Portals API. The first column in this table gives the name for the function, the second column gives a brief description of the operation implemented by the function, and the third column identifies the section where the function is defined.

Table 4 summarizes the return codes used by functions defined by the Portals API. All of these constants are integer values. The first column of this table gives the symbolic name for the constant, the second column gives a brief description of the value, and the third column identifies the functions that can return this value.

Table 5 summarizes the remaining constant values introduced by the Portals API. The first column in this table presents the symbolic name for the constant, the second column gives a brief description of the value, the third column identifies the type for the value, and the fourth column identifies the sections in which the value is mentioned.

Table 3: Functions Defined by the Portals 3.0 API

Name	Operation	Section
PtlACEntry	update an entry in an access control table	3.9
PtlEQAlloc	create an event queue	3.8
PtlEQCount	get the number events in an event queue	3.8
PtlEQGet	get the next event from an event queue	3.8
PtlEQFree	release the resources for an event queue	3.8
PtlEQWait	wait for a new event in an event queue	3.8
PtlFini	shutdown the Portals API	3.3
PtlGet	perform a get operation	3.10
PtlGetId	get the id for the current process	3.4
PtlInit	initialize the Portals API	3.3
PtlMDAttach	create a memory descriptor and attach it to a match entry	3.7
PtlMDBind	create a free-floating memory descriptor	3.7.4
PtlMDInsert	create a memory descriptor and insert it in a list	3.7
PtlMDUnlink	remove a memory descriptor from a list and release its resources	3.7
PtlMDUpdate	update a memory descriptor	3.7
PtlMEAttach	create a match entry and attach it to a portal table	3.6
PtlMEInsert	create a match entry and insert it in a list	3.6
PtlMEUnlink	remove a match entry from a list and release its resources	3.6
PtlNIBarrier	barrier synchronization for a process group	3.5
PtlNIDist	get the distance to another process	3.5
PtlNIFini	shutdown a network interface	3.5
PtlNIHandle	get the network interface handle for an object	3.5
PtlNIInit	initialize a network interface	3.5
PtlNIStatus	read a network interface status register	3.5
PtlPut	perform a put operation	3.10
PtlTransId	translate id	3.4

Table 4: Function Return Codes for the Portals 3.0 API

Name	Meaning	Functions
PTL_AC_INV_INDEX	invalid access control table index	PtlACEEntry
PTL_ADDR_UNKNOWN	unknown process address	PtlTransId
PTL_EQ_DROPPED	at least one event has been dropped	PtlEQGet, PtlWait
PTL_EQ_EMPTY	no events available in an event queue	PtlEQGet
PTL_FAIL	error during initialization or cleanup	PtlInit, PtlFini
PTL_ILL_MD	illegal memory descriptor values	PtlMDAttach, PtlMDInsert, PtlMDBind, PtlMDUpdate
PTL_INIT_DUP	duplicate initialization of an interface	PtlNIIInit
PTL_INIT_INV	initialization of an invalid interface	PtlNIIInit
PTL_INV_ASIZE	invalid access control table size	PtlNIIInit
PTL_INV_EQ	invalid event queue handle	PtlMDUpdate, PtlEQFree, PtlEQCount, PtlEQGet
PTL_INV_HANDLE	invalid handle	PtlNIHandle
PTL_INV_MD	invalid memory descriptor handle	PtlMDInsert, PtlMDUnlink, PtlMDUpdate
PTL_INV_ME	invalid match entry handle	PtlMDAttach, PtlMDInsert
PTL_INV_NI	invalid network interface handle	PtlNIBarrier, PtlNIDist, PtlNIFini, PtlMDBind, PtlEQAlloc
PTL_INV_PROC	invalid process identifier	PtlNIDist, PtlMEAttach, PtlMEInsert, PtlACEEntry, PtlPut, PtlGet
PTL_INV_PSIZE	invalid portal table size	PtlNIIInit
PTL_INV_PTINDEX	invalid portal table index	PtlMEAttach
PTL_INV_REG	invalid status register	PtlNIStatus
PTL_INV_SR_INDX	invalid status register index	PtlNIStatus
PTL_ML_TOOLONG	match list too long	PtlMEInsert
PTL_NOINIT	uninitialized API	<i>all</i> , except PtlInit
PTL_NOSPACE	insufficient memory	PtlNIIInit, PtlMDAttach, PtlMDInsert, PtlMDBind, PtlEQAlloc, PtlMEAttach, PtlMEInsert
PTL_NOUPDATE	no update was performed	PtlMDUpdate
PTL_OK	success	<i>all</i>
PTL_SEGV	addressing violation	PtlGetId, PtlTransId, PtlNIIInit, PtlNIStatus, PtlNIDist, PtlNIHandle, PtlMEAttach, PtlMEInsert, PtlMDAttach, PtlMDInsert, PtlMDBind, PtlMDUpdate, PtlEQAlloc, PtlEQCount, PtlEQGet, PtlEQWait

Table 5: Other Constants Defined by the Portals 3.0 API

Name	Meaning	Base type	Section
PTL_ACK_REQ	request an acknowledgement	ptl_ack_req_t	3.10.1
PTL_ADDR_BOTH	nid, pid and gid, rid process address	ptl_addr_kind_t	3.4.1
PTL_ADDR_GID	gid, rid process address	ptl_addr_kind_t	3.4.1
PTL_ADDR_NID	nid, pid process address	ptl_addr_kind_t	3.4.1
PTL_EQ_NONE	a NULL event queue handle	ptl_handle_eq_t	3.7.6
PTL_EVENT_GET	get event	ptl_event_kind_t	3.8.1
PTL_EVENT_PUT	put event	ptl_event_kind_t	3.8.1
PTL_EVENT_REPLY	reply event	ptl_event_kind_t	3.8.1
PTL_EVENT_ACK	acknowledgement event	ptl_event_kind_t	3.8.1
PTL_EVENT_SENT	sent event	ptl_event_kind_t	3.8.1
PTL_ID_ANY	wildcard for process id fields	ptl_id_t	3.6.1
PTL_IFACE_DEFAULT	default interface	ptl_interface_t	3.2.5
PTL_INS_AFTER	insert after	ptl_ins_pos_t	3.6.2
PTL_INS_BEFORE	insert before	ptl_ins_pos_t	3.6.2
PTL_MD_ACK_DISABLE	a flag to disable acknowledgements	int	3.7.1
PTL_MD_MANAGE_REMOTE	a flag to enable the use of remote offsets	int	3.7.1
PTL_MD_OP_GET	a flag to enable get operations	int	3.7.1
PTL_MD_OP_PUT	a flag to enable put operations	int	3.7.1
PTL_MD_THRESH_INF	infinite threshold for a memory descriptor	int	3.7.1
PTL_MD_TRUNCATE	a flag to enable truncation of a request	int	3.7.1
PTL_NOACK_REQ	request no acknowledgement	ptl_ack_req_t	3.10.1
PTL_PT_INDEX_ANY	wildcard for portal indexes	ptl_pt_index_t	3.9.1
PTL_RETAIN	disable unlinking	ptl_unlink_t	3.6.1
PTL_SR_DROP_COUNT	index for the dropped count register	ptl_sr_index_t	3.2.7
PTL_UNLINK	enable unlinking	ptl_unlink_t	3.6.1

4 The Semantics of Message Transmission

The portals API uses four types of messages: put requests, acknowledgements, get requests, and replies. In this section, we describe the information passed on the wire for each type of message. We also describe how this information is used to process incoming messages.

4.1 Sending Messages

Table 6 summarizes the information that is transmitted for a put request. The first column provides a descriptive name for the information, the second column provides the type for this information, the third column identifies the source of the information, and the fourth column provides additional notes. Most information that is transmitted is obtained directly from the *PtlPut* operation. Notice that the handle for the memory descriptor used in the *PtlPut* operation is transmitted even though this value cannot be interpreted by the target. A value of anything other than PTL_MD_NONE, is interpreted as a request for an acknowledgement.

Information	Type	<i>PtlPut</i> argument	Notes
operation	int		indicates a put request
initiator	ptl_process_id_t		local information
target	ptl_process_id_t	target	
portal index	ptl_pt_index_t	portal	
cookie	ptl_ac_index_t	cookie	
match bits	ptl_match_bits_t	match_bits	
offset	ptl_size_t	offset	
memory desc	ptl_handle_md_t	mem_desc	no ack if PTL_MD_NONE
length	ptl_size_t	mem_desc	length member
data	bytes	mem_desc	start and length members

Table 6: Information Passed in a Put Request

Table 7 summarizes the information transmitted in an acknowledgement. Most of the information is simply echoed from the put request. Notice that the initiator and target are obtained directly from the put request, but are swapped in generating the acknowledgement. The only new piece of information in the acknowledgement is the manipulated length which is determined as the put request is satisfied.

Information	Type	Put Information	Notes
operation	int		indicates an acknowledgement
initiator	ptl_process_id_t	target	
target	ptl_process_id_t	initiator	
portal index	ptl_pt_index_t	portal index	echo
match bits	ptl_match_bits_t	match bits	echo
offset	ptl_size_t	offset	echo
memory desc	ptl_handle_md_t	memory desc	echo
requested length	ptl_size_t	length	echo
manipulated length	ptl_size_t		obtained from the operation

Table 7: Information Passed in an Acknowledgement

Table 8 summarizes the information that is transmitted for a get request. Like the information transmitted in a put request, most of the information transmitted in a get request is obtained directly from the *PtlGet* operation. Unlike put requests, get requests do not include the event queue handle. In this case, the reply is generated whenever the operation succeeds and the memory descriptor must not be unlinked until the reply is received. As such, there is no advantage to explicitly sending the event queue handle.

Table 9 summarizes the information transmitted in a reply. Like an acknowledgement, most of the information is simply echoed from the get request. The initiator and target are obtained directly from the get request, but are swapped

Information	Type	<i>PtlGet</i> argument	Notes
operation	int		indicates a get operation
initiator	ptl_process_id_t		local information
target	ptl_process_id_t	target	
portal index	ptl_pt_index_t	portal	
cookie	ptl_ac_index_t	cookie	
match bits	ptl_match_bits_t	match_bits	
offset	ptl_size_t	offset	
memory desc	ptl_handle_md_t	mem_desc	
length	ptl_size_t	mem_desc	length member

Table 8: Information Passed in a Get Request

in generating the acknowledgement. The only new information in the acknowledgement are the manipulated length and the data which are determined as the get request is satisfied.

Information	Type	Put Information	Notes
operation	int		indicates an acknowledgement
initiator	ptl_process_id_t	target	
target	ptl_process_id_t	initiator	
portal index	ptl_pt_index_t	portal index	echo
match bits	ptl_match_bits_t	match bits	echo
offset	ptl_size_t	offset	echo
memory desc	ptl_handle_md_t	memory desc	echo
requested length	ptl_size_t	length	echo
manipulated length	ptl_size_t		obtained from the operation
data	bytes		obtained from the operation

Table 9: Information Passed in a Reply

4.2 Receiving Messages

When an incoming message arrives on a network interface, the runtime system first checks that the target process identified in the request is a valid process that has initialized the network interface (i.e., that the target process has a valid portal table). If this test fails, the runtime system discards the message and increments the dropped message count for the interface. The remainder of the processing depends on the type of the incoming message. Put and get messages are subject to access control checks and translation (searching a match list), while acknowledgement and reply messages bypass the access control checks and the translation step.

Acknowledgement messages include a handle for the event queue where the event should be recorded. Upon receipt of an acknowledgement, the runtime system only needs to confirm that the event queue still exists and that there is space for another event. Should the event queue no longer exist or if there is not sufficient space in the event queue, the message is simply discarded and the dropped message count for the interface is incremented. Otherwise, the runtime system builds an acknowledgement event from the information in the acknowledgement message and adds it to the event queue.

Reception of reply messages is also relatively straightforward. Each reply message includes a handle for a memory descriptor. If this descriptor exists, it is used to receive the message. A reply message will be dropped if the memory descriptor identified in the request doesn't exist or if the event queue in the memory descriptor has no space and is not PTL_EQ_NONE. In either of these cases, the dropped message count for the interface is incremented. These are the only reasons for dropping reply messages. Every memory descriptor accepts and truncates incoming reply messages, eliminating the other potential reasons for rejecting a reply message.

The critical step in processing an incoming put or get request involves mapping the request to a memory descriptor. This step starts by using the portal index in the incoming request to identify a list of match entries. This list of match entries is searched in order until a match entry is found whose match criteria matches the match bits in the incoming

request and whose **first** memory descriptor accepts the request.

Because acknowledge and reply messages are generated in response to requests made by the process receiving these messages, the checks performed by the runtime system for acknowledgements and replies are minimal. In contrast, put and get messages are generated by remote processes and the checks performed for these messages are more extensive. Incoming put or get messages may be rejected because:

- the portal index supplied in the request is not valid;
- the cookie supplied in the request is not a valid access control entry;
- the access control entry identified by the cookie does not match the identifier of the requesting process;
- the access control entry identified by the cookie does not match the identifier of the requesting user;
- the access control entry identified by the access control entry does not match the portal index supplied in the request; or
- the match bits supplied in the request do not match any of the match entries with a memory descriptor that accepts the request.

In all cases, if the message is rejected, the incoming message is discarded and the dropped message count for the interface is incremented.

A memory descriptor may reject an incoming request for any of the following reasons:

- the PTL_MD_PUT or PTL_MD_GET option has not been enabled and the operation is put or get, respectively;
- the length specified in the request is too long for the memory descriptor and the PTL_MD_TRUNCATE option has not been enabled;
- the event queue is not PTL_EQ_NONE and there is no space for a new event.

5 Examples

In this section we present several example to illustrate expected usage patterns for the Portals 3.0 API. The first example describes how to implement parallel servers using the features of the Portals 3.0 API. This example covers the access control list and the use of remote managed offsets. The second example presents an approach to dealing with dropped requests. This example covers aspects of match lists and memory descriptors. The final example covers message reception in MPI. This example illustrates more sophisticated uses of matching and a procedure to update a memory descriptor.

5.1 Parallel File Servers

Figure 5 illustrates the logical structure of a parallel file server. In this case, the parallel server consists of four servers that stripe application data across four disks. We would like to present applications with the illusion that the file server is a single entity. We will assume that all of the processes that constitute the parallel server are in a single group and that this group is unique to the parallel server.

When an application establishes a connection to the parallel file server, it will allocate a portal and access control list entry for communicating with the server. The access control list entry will include the portal and match any process in the parallel file server's group, so all of the file server processes will have access to the portal. The portal information and access control entry will be sent to the file server at this time. If the application and server need to have multiple, concurrent I/O operations, they can use additional portals or match entries to keep the operations from interfering with one another.

When an application initiates an I/O operation, it first builds a memory descriptor that describes the memory region involved in the operation. This memory descriptor will enable the appropriate operation (put for read operations and get for write operations) and enable the use of remote offsets (this lets the servers decide where their data should be placed in the memory region). After creating the memory descriptor and linking it into the appropriate portal entry, the application sends a read or write request (using *PtlPut*) to one of the file server processes. The file server processes

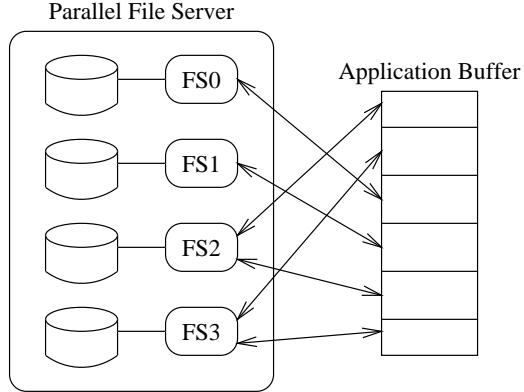

Figure 5: Parallel File Server

can then use put or get operations with the appropriate offsets to fill or retrieve the contents of the application’s buffer. To know when the operation has completed, the application can add an event queue to the memory descriptor and add up the lengths of the remote operations until the sum is the size of the requested I/O operation.

5.2 Dealing with Dropped Requests

If a process does not anticipate unexpected requests, they will be discarded. Applications using the Portals API can query the dropped count for the interface to determine the number of requests that have been dropped (see Section 3.5.4). While this approach minimizes resource consumption, it does not provide information that might be critical in debugging the implementation of a higher level protocol.

To keep track of more information about dropped requests, we use a memory descriptor that truncates each incoming request to zero bytes and logs the “dropped” operations in an event queue. Note that the operations are not dropped in the Portals sense, because the operation succeeds.

The following code fragment illustrates an implementation of this approach. In this case, we assume that a thread is launched to execute the function `watch_drop`. This code starts by building an event queue to log truncated operations and a memory descriptor to truncate the incoming requests. This example only captures “dropped” requests for a single portal. In a more realistic situation, the memory descriptor would be appended to the match list for every portal. We also assume that the thread is capable of keeping up with the “dropped” requests. If this is not the case, we could use a finite threshold on the memory descriptor to capture the first few dropped requests.

```
#include <stdio.h>
#include <stdlib.h>
#include <portals.h>

#define DROP_SIZE 32 /* number of dropped requests to track */

int watch_drop( ptl_handle_ni_t ni, ptl_pt_index_t index ) {
    ptl_handle_eq_t drop_events;
    ptl_event_t event;
    ptl_handle_md_t drop_em;
    ptl_md_t drop_desc;
    ptl_process_id_t any_proc;
    ptl_handle_me_t match_any;

    /* create the event queue */
    if( PtIEQAlloc(ni, DROP_SIZE, &drop_events) != PTL_OK ) {
        fprintf( stderr, "Couldn't create the event queue\n" );
        exit( 1 );
    }
}
```

```

/* build a match entry */
any_proc.pid_nid = PTL_ADDR_GID;
any_proc.gid = PTL_ID_ANY;
any_proc.rid = PTL_ID_ANY;
PtlMEAttach( index, any_proc, 0, ~(ptl_match_bits_t)0, PTL_RETAIN,
             &match_any );

/* create the memory descriptor */
drop_desc.start = NULL;
drop_desc.length = 0;
drop_desc.threshold = PTL_MD_THRESH_INF;
drop_desc.options = PTL_MD_OP_PUT | PTL_MD_OP_GET | PTL_MD_TRUNCATE;
drop_desc.user_ptr = NULL;
drop_desc.eventq = drop_events;
if( PtlMDAttach(match_any, drop_desc, &drop_em) != PTL_OK ) {
    fprintf( stderr, "Couldn't create the memory descriptor\n" );
    exit( 1 );
}

/* watch for "dropped" requests */
while( 1 ) {
    if( PtlEQWait( drop_events, &event ) != PTL_OK ) break;
    fprintf( stderr, "Dropped request from gid = %d, rid = %d\n",
             event.initiator.gid, event.initiator.rid );
}

```

5.3 Message Transmission in MPI

We conclude this section with a fairly extensive example that describes an approach to implementing message transmission for MPI. Like many MPI implementations, we distinguish two message transmission protocols: a short message protocol and a long message protocol. We use the constant `MPI_LONG_LENGTH` to determine the size of a long message.

For small messages, the sender simply sends the message and presumes that the message will be received (i.e., the receiver has allocated a memory region to receive the message body). For large messages, the sender also sends the message, but does not presume that the message body will be saved. Instead, the sender builds a memory descriptor for the message and enables get operations on this descriptor. If the target does not save the body of the message, it will record an event for the put operation. When the process later issues a matching MPI receive, it will perform a get operation to retrieve the body of the message.

The following code presents a function that implements the send side of the protocol. The global variable `EndGet` is the last match entry attached to the portal index used for posting long messages. This entry does not match any incoming requests (i.e., the memory descriptor rejects all get operations) and is built during initialization of the MPI library. The other global variable, `MPI_NI`, is a handle for the network interface used by the MPI implementation.

```

extern ptl_handle_me_t EndGet;
extern ptl_handle_ni_t MPI_NI;

void MPISend( void *buf, ptl_size_t len, void *data, ptl_handle_eq_t eventq,
              ptl_process_id target, ptl_match_bits_t match )
{
    ptl_handle_md_t send_handle;
    ptl_md_t mem_desc;
    ptl_ack_req_t want_ack = PTL_NOACK_REQ;

    mem_desc.start = buf;
    mem_desc.length = len;
    mem_desc.threshold = 1;

```

```

mem_desc.options = PTL_MD_GET_OP;
mem_desc.user_ptr = data;
mem_desc.eventq = eventq;

if( len > MPI_LONG_LENGTH ) {
    ptl_handle_me_t me_handle;

    /* add a match entry to the end of the get list */
    PtlMEInsert( target, match, 0, PTL_UNLINK, PTL_INS_BEFORE, EndGet, &me_handle );
    PtlMDAttach( me_handle, mem_desc, PTL_UNLINK, NULL );

    /* we want an ack for long messages */
    want_ack = PTL_ACK_REQ;
}

/* create a memory descriptor and send it */
PtlMDBind( MPI_NI, mem_desc, &send_handle );
PtlPut( send_handle, want_ack, target, MPI_SEND_PINDEX, MPI_AINDEX, match, 0 );
}

```

The *MPISend* function returns as soon as the message has been scheduled for transmission. The event queue argument, `eventq`, can be used to determine the disposition of the message. Assuming that `eventq` is not `PTL_EQ_NONE`, a `PTL_EVENT_SENT` event will be recorded for each message as the message is transmitted. For small messages, this is the only event that will be recorded in `eventq`. In contrast, long messages include an explicit request for an acknowledgement. If the `target` process has posted a matching receive, the acknowledgement will be sent as the message is received. If a matching receive has not been posted, the message will be discarded and no acknowledgement will be sent. When the `target` process later issues a matching receive, the receive will be translated into a get operation and a `PTL_EVENT_GET` event will be recorded in `eventq`.

Figure 6 illustrates the organization of a match list for receiving MPI messages. The match list starts with entries that match the preposted MPI receives (these entries are not shown in Figure 6); followed by a match entry that rejects all incoming requests, called the *RcvMark*; followed by two match entries that match all incoming requests. The last two match entries are used for unexpected messages, i.e., messages that do not match any of the receives that have been posted by the local MPI process. The first of these handles short messages by saving the body of the message, while the second handles long messages by discarding the message body. All of the memory descriptors associated with these match entries share a common event queue to ensure that unexpected messages are processed in arrival order.

When the local MPI process posts an MPI receive, a new match entry is inserted before the *RcvMark* entry and, as such, after all of the previously posted receives. This ensures that preposted receives are matched in the order that they were posted (a requirement of MPI). Inserting an entry for a preposted receive is not a matter of simply inserting a match entry before the *RcvMark*. You must first check to see if a matching message has arrived before adding the new entry to match list. The trick is to avoid the race condition that results from the possibility that a matching message arrives after you have searched the match list, but before you have inserted the preposted receive. The function presented in

The following code presents a function that avoids this race condition. The code starts by creating a memory descriptor and a match entry which is inserted before the *RcvMark*. Because the memory descriptor's `threshold` is initially set to zero, the memory descriptor will not respond to any incoming operations. After inserting the new match entry, the code searches for a matching message that has already been received. If a match is found, the memory descriptor and match entry are released and the function returns. Otherwise, the code conditionally updates the `threshold` member of the memory descriptor. The update is predicated by the condition that no unexpected messages have arrived since the start of the search.

```

extern ptl_handle_eq_t UnexpQueue;
extern ptl_handle_me_t RcvMark;
extern ptl_handle_me_t ShortMatch;

```

```

typedef struct event_list_tag {

```

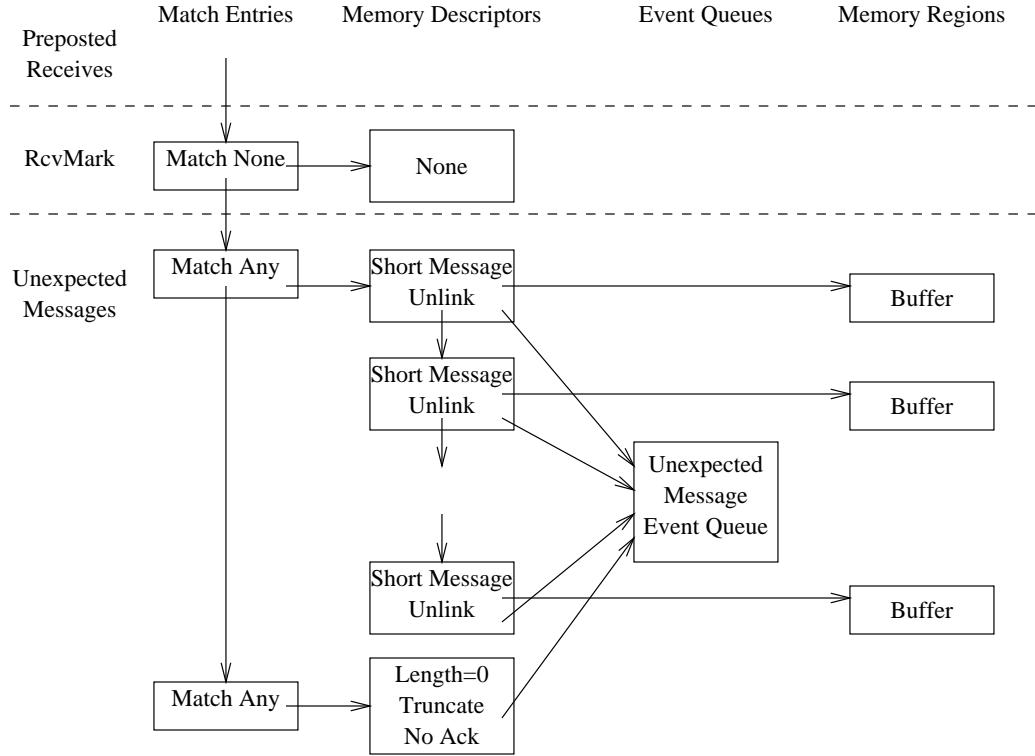

Figure 6: Message Reception in MPI

```

ptl_event_t      event;
struct event_list_tag *next;
} event_list;

extern event_list Rcvd;

void AppendRcvd( ptl_event_t event )
{
    /* append an event onto the Rcvd list */
}

int SearchRcvd( void *buf, ptl_size_t len, ptl_process_id_t sender, ptl_match_bits_t match,
                ptl_match_bits_t ignore, ptl_event_t *event )
{
    /* Search the Rcvd event queue, looking for a message that matches the requested message.
     * If one is found, remove the event from the Rcvd list and return it. */
}

typedef enum { RECEIVED, POSTED } receive_state;

receive_state CopyMsg( void *buf, ptl_size_t length, ptl_event_t event, ptl_md_t md_buf )
{
    ptl_md_t md_buf;
    ptl_handle_me_t me_handle;

    if( event.rlength >= MPI_LONG_LENGTH ) {
        PtlIMDBind( MPI_NI, md_buf, &md_handle );
        PtlGet( event.initiator, MPI_GET_PINDEX, 0, event.match_bits, MPI_AINDEX, md_handle );
        return POSTED;
    }
}

```

```

} else {
    /* copy the message and recycle the buffer */
    memcpy( buf, event.md_desc.start, len );
    event.md_desc.threshold = 1;
    PtIMDAAttach( ShortMatch, event.md_desc, PTL_UNLINK, NULL );
    return RECEIVED;
}
}

receive_state MPIreceive( void *buf, ptl_size_t len, void *MPI_data, ptl_handle_eq_t eventq,
                        ptl_process_id_t sender, ptl_match_bits_t match, ptl_match_bits_t ignore )
{
    ptl_md_t md_buf;
